Chapter 10

Ch. **10**, Posets, lattices, and complete lattices

# Order theory

- Order theory emerged from the work of George Boole, Ernst Schröder, Charles Peirce, and was mainly developed by Garrett Birkhoff [Birkhoff, 1940, 1995].
- Order theory is an abstraction of set theory where  $\in$  is expressed in terms of  $\subseteq$   $(x \in S \Leftrightarrow \{x\} \subseteq S)$  and  $\subseteq$  is abstracted as a partial order  $\sqsubseteq$
- The abstract partial order 
  retains the essential properties of inclusion (reflexive, antisymmetric, and transitive).
- Many theorems of set theory remain valid, but not all, and this widely broaden the scope of applicability of order theory (see introductions in [Birkhoff, 1940, 1995; Davey and Priestley, 1990, 2002; Grätzer, 2011]).

en.wikipedia.org/wiki/Order_theory
en.wikipedia.org/wiki/Glossary_of_order_theory
```

# Partially ordered set (Poset)

■ A *poset*  $\langle \mathbb{P}, \sqsubseteq \rangle$  is a set  $\mathbb{P}$  equipped with a *partial order*  $\sqsubseteq$  which is

```
Reflexive: \forall x \in \mathbb{P} . x \sqsubseteq x;
Antisymmetric: \forall x, y \in \mathbb{P} . ((x \sqsubseteq y) \land (y \sqsubseteq x)) \Rightarrow (x = y);
Transitive: \forall x, y, z \in \mathbb{P} . ((x \sqsubseteq y) \land (y \sqsubseteq z)) \Rightarrow (x \sqsubseteq z).
```

en.wikipedia.org/wiki/Partially ordered set

#### Total order

- Two elements x and y are *comparable* when either  $x \sqsubseteq y$  or  $y \sqsubseteq x$  and *incomparable* when neither  $x \sqsubseteq y$  nor  $y \sqsubseteq x$ .
- A partial order 

  is total whenever any two elements are comparable.

*Total:* 
$$\forall x, y \in \mathbb{P}$$
 .  $(x \sqsubseteq y) \lor (y \sqsubseteq x)$ .

en.wikipedia.org/wiki/Total\_order

# Strict partial order

- A strict partial order  $\sqsubset$  is irreflexive  $(\forall x \in \mathbb{P} : x \neq x)$  and transitive.
- If  $\sqsubseteq$  is a partial order then  $x \sqsubseteq y \triangleq x \sqsubseteq y \land x \neq y$  is strict.
- If  $\Box$  is a strict partial order then  $x \sqsubseteq y \triangleq x \sqsubset y \lor x = y$  is a partial order.

en.wikipedia.org/?title=Strict\_partial\_order&redirect=no

#### Preorder

- A preorder ≤ is reflexive and transitive.
- Then  $x \equiv y \triangleq x \le y \land y \le x$  is an *equivalence relation* (reflexive, symmetric  $(\forall x, y \in \mathbb{P} : x \equiv y \Rightarrow y \equiv x)$ , and transitive).
- The equivalence class of  $x \in \mathbb{P}$  for the equivalence relation  $\equiv$  is  $[x]_{\equiv} \triangleq \{y \in \mathbb{P} \mid x \equiv y\}.$
- The *quotient* of  $\mathbb{P}$  by  $\equiv$  is  $\mathbb{P}|_{\equiv} \triangleq \{[x]_{\equiv} \mid x \in \mathbb{P}\}.$
- The extension of the preorder  $\leq$  to the quotient  $\mathbb{P}|_{\equiv}$  is

$$[x]_{\scriptscriptstyle \equiv} \leq_{\scriptscriptstyle \equiv} [y]_{\scriptscriptstyle \equiv} \Leftrightarrow \exists x' \in [x]_{\scriptscriptstyle \equiv}, y' \in [y]_{\scriptscriptstyle \equiv} . \ x' \leq y'$$

• If  $\leq$  is a preorder on  $\mathbb{P}$  then  $\leq_{\underline{\ }}$  is a partial order on  $\mathbb{P}|_{\underline{\ }}$ .

```
en.wikipedia.org/wiki/Preorder
en.wikipedia.org/wiki/Equivalence_relation
en.wikipedia.org/wiki/Equivalence class
```

# Equality

 Equality = is the only relation which is both a partial order and an equivalence relation.

en.wikipedia.org/wiki/Equality\_(mathematics)

Hasse diagrams

# Hasse diagrams

■ Finite posets  $\langle \mathbb{P}, \sqsubseteq \rangle$  can be represented by a Hasse diagram

- This is a set of points  $\{p_x \mid x \in \mathbb{P}\}\$  in the plane, different two by two, and such that
  - if  $x \sqsubset y$  then  $p_x$  is strictly below  $p_y$ ;
  - $p_x$  and  $p_y$  are linked by a segment when  $x \lessdot y$  (y covers x) where  $x \lessdot y \triangleq x \sqsubset y \land \nexists z \in \mathbb{P}$  .  $x \sqsubset z \land z \sqsubset y$ .
- is derived from < by reflexivity and transitivity.</li>
   Two unlinked elements are incomparable.

en.wikipedia.org/wiki/Hasse\_diagram

Least upper bound (lub), greatest lower bound (glb), minimum, maximum, infimum, supremum (Section **10.3**)

#### Bounds and extrema

- Let  $\langle \mathbb{P}, \sqsubseteq \rangle$  be a poset and  $S \in \wp(\mathbb{P})$  be a subset.
- This subset S has

An upper bound u: if and only if  $u \in \mathbb{P}$  and  $\forall x \in S . x \sqsubseteq u$ ;

A least upper bound (lub/join)  $\sqcup S$ : if and only if

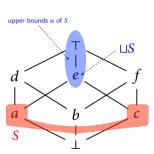

- $\sqcup S \in \mathbb{P}$
- $\sqcup S$  is an upper bound of S (i.e.  $\forall x \in S$  .  $x \sqsubseteq \sqcup S$ )
- $\sqcup S$  is smaller that other upper bound of S (i.e.  $\forall u \in \mathbb{P}$  .  $(\forall x \in S : x \sqsubseteq u) \Rightarrow (\sqcup S \sqsubseteq u)$ .

 $\sqcup \{x, y\}$  is denoted with the infix notation  $x \sqcup y$ ;

A maximum M: if and only if  $M = \sqcup S \in S$ ;

A supremum T: if and only if  $T = \sqcup \mathbb{P} \in \mathbb{P}$ .

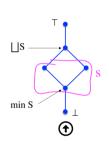

en.wikipedia.org/wiki/Upper\_and\_lower\_bounds en.wikipedia.org/wiki/Least-upper-bound\_property en.wikipedia.org/wiki/Maxima\_and\_minima en.wikipedia.org/wiki/Infimum and supremum

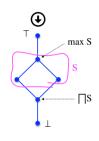

Duality principle (Section 10.4)

#### Order dual

- The order dual of an order-theoretic definition or statement is obtained by replacing
  - by its inverse ⊒,
  - upper by lower,
  - least by greatest,
  - U by □,
  - □ by □,
  - join by meet,
  - meet by join,
  - maximum by minimum,
  - etc.

en.wikipedia.org/wiki/Duality\_(order\_theory)

# Duality principle

 If a definition or statement is valid for all partially ordered sets then the dual definition or dual statement is also valid for all partially ordered sets [Birkhoff, 1940, 1995].

**Example 10.1** Let 
$$f \in \langle A, \leqslant \rangle \xrightarrow{\sim} \langle B, \sqsubseteq \rangle$$
 be increasing ie *i.e.*  $\forall x, y \in A : (x \leqslant y) \Rightarrow (f(x) \sqsubseteq f(y))$ 

- The dual of "f is increasing" is "f is increasing".
- Note that if duality is applied to  $\langle A, \leqslant \rangle$  or  $\langle B, \sqsubseteq \rangle$  only, then the semi-dual of "f is increasing" would be "f is decreasing" i.e.  $\forall x, y \in A . (x \leqslant y) \Rightarrow (f(x) \supseteq f(y)).$

en.wikipedia.org/wiki/Duality\_principle

Lattices

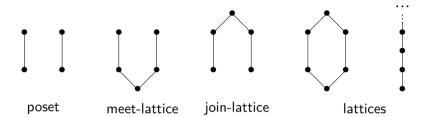

#### Lattices

Lattices are posets with the following properties.

- Join semilattice:  $\forall x, y \in \mathbb{P}$  .  $x \sqcup y$  exists in  $\mathbb{P}$  (hence any non-empty finite subset of  $\mathbb{P}$  has a lub);
- Meet semilattice:  $\forall x, y \in \mathbb{P}$  .  $x \sqcap y$  exists in  $\mathbb{P}$  (hence any non-empty finite subset of  $\mathbb{P}$  has a glb);
- Lattice:  $\forall x, y \in \mathbb{P}$  .  $x \sqcup y$  and  $x \sqcap y$  exist in  $\mathbb{P}$  (hence any non-empty finite subset of  $\mathbb{P}$  has a lub/join and a glb/meet).

```
en.wikipedia.org/wiki/Semilattice
en.wikipedia.org/wiki/Lattice (order)
```

# Examples of lattices

#### Joins and meets of lattices

- Lattices have unique joins/meets of two-elements hence, by associativity of finite subsets.
- For example  $\langle \mathbb{N}, \leq \rangle$  is a lattice where
  - the glb/meet is min
  - the lub/join is max

taken on non-empty finite subsets of N.

# Algebraic definition of lattices

The lub □ and glb □ of a lattice (P, □) have the following properties.

$$x\sqcap x=x$$
  $x\sqcup x=x$  idempotency  $x\sqcap y=y\sqcap x$   $x\sqcup y=y\sqcup x$  commutativity  $x\sqcap (y\sqcap z)=(x\sqcap y)\sqcap z$   $x\sqcup (y\sqcup z)=(x\sqcup y)\sqcup z$  associativity  $(x\sqcap y)\sqcup x=x$   $(x\sqcup y)\sqcap x=x$  distributivity

Conversely, a set equipped with binary operations 
 □ an 
 □ satisfying the above properties is a lattice by defining

$$x \sqsubseteq y \triangleq x \sqcap y = x$$
 (or equivalently  $x \sqcup y = y$ ).

en.wikipedia.org/wiki/Algebraic\_structure

Complete lattices (Section **10.6**)

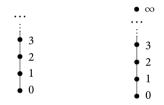

#### Complete lattice

- A complete lattice is a poset  $\langle \mathbb{P}, \sqsubseteq \rangle$  in which any subset  $S \in \wp(\mathbb{P})$  has a lub/join  $\sqcup S$  (not only the finite ones).
- Therefore a complete lattice has a supremum  $\top = \sqcup \mathbb{P}$  and an infinum  $\bot = \sqcup \emptyset$ .
- Any element x of  $\mathbb{P}$  is an upper bound of  $\emptyset$  since  $\forall y \in \emptyset$  .  $y \sqsubseteq x$ . So the lub of  $\emptyset$  is the least element of  $\mathbb{P}$ .

en.wikipedia.org/wiki/Complete\_lattice

# Examples of complete lattice

- $\langle \mathbb{N}, \leq \rangle$  is not a complete lattice since  $\mathbb{N}$  has no lub.
- $(\mathbb{N} \cup {\infty})$ ,  $\leq$  where  $\forall n \in \mathbb{N}$  .  $n < \infty \leq \infty$  is a complete lattice with supremum  $\infty$  and infimum 0.

■ The powerset of a set S is a complete lattice  $\langle \wp(S), \subseteq, \emptyset, S, \cup, \cap \rangle$ .

# Properties of complete lattices (Exercise 10.4)

- A complete lattice  $\langle \mathbb{P}, \sqsubseteq, \bot, \top, \sqcup \rangle$  has a glb  $\sqcap$  for arbitrary subsets.
- $\blacksquare \quad \sqcap S = \sqcup \{\ell \mid \forall x \in S : \ell \sqsubseteq x\}$

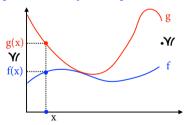

# Properties of complete lattices (Exercise 10.5)

■ In a complete lattice  $\langle \mathbb{P}, \sqsubseteq, \bot, \top, \sqcup \rangle$ , if  $X, Y \in \wp(\mathbb{P})$  and  $X \subseteq Y$  then  $\sqcup X \sqsubseteq \sqcup Y$ .

Pointwise extension

#### Pointwise extension

- Let  $\langle \mathbb{P}, \sqsubseteq \rangle$  be a poset and S be a set.
- The pointwise extension  $\sqsubseteq$  of  $\sqsubseteq$  to S is  $\langle S \to \mathbb{P}, \, \sqsubseteq \rangle$  where  $f \sqsubseteq g$  if and only if  $\forall x \in S . f(x) \sqsubseteq g(x)$ .
- The pointwise join is  $f \dot{\sqcup} g \triangleq x \in S \mapsto f(x) \sqcup g(x)$
- The pointwise meet is  $f \cap g \triangleq x \in S \mapsto f(x) \cap g(x)$ , etc.

■ The pointwise extension of <u>i</u> is denoted <u>i</u>, that of <u>i</u> is <u>i</u>, *etc*.

en.wikipedia.org/wiki/Pointwise

# Properties of the pointwise extension

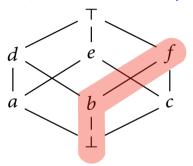

- The pointwise extension of a poset (respectively semi-lattice, lattice, complete lattice, etc.) is a poset (respectively semi-lattice, lattice, complete lattice, etc.).
- Let  $\langle \mathbb{P}, \sqsubseteq, \bot, \top, \sqcup, \sqcap \rangle$  be a complete lattice.
  - The increasing functions  $\mathbb{P} \stackrel{\checkmark}{\longrightarrow} \mathbb{P} \triangleq \{ f \in \mathbb{P} \rightarrow \mathbb{P} \mid \forall x, y \in \mathbb{P} : (x \sqsubseteq y) \Rightarrow f(x) \sqsubseteq f(y) \} \},$
  - The arbitrary join preserving functions  $\mathbb{P} \stackrel{\sqcup}{\longrightarrow} \mathbb{P} \triangleq \{ f \in \mathbb{P} \to \mathbb{P} \mid \forall S \in \wp(\mathbb{P}) : (\sqcup S \in \mathbb{P}) \Rightarrow (\sqcup f(S) \in \mathbb{P} \land f(\sqcup S) = \sqcup f(S)) \}$  where  $f(S) \triangleq \{ f(x) \mid x \in S \}$
  - Dually, the arbitrary meet preserving functions  $\mathbb{P} \stackrel{\sqcap}{\longrightarrow} \mathbb{P}$  are a complete lattice for the pointwise ordering

$$f \stackrel{.}{\sqsubseteq} g \Leftrightarrow \forall x \in \mathbb{P} \ . \ f(x) \stackrel{.}{\sqsubseteq} g(x)$$

Chain (Section 10.8)

#### Chains I

■ A chain C of a poset  $\langle \mathbb{P}, \sqsubseteq \rangle$  is a subset of the poset  $\mathbb{P}$  such that any two elements of the chain are comparable i.e.  $C \subseteq \mathbb{P} \land \forall x, y \in C$ .  $x \sqsubseteq y \lor y \sqsubseteq x$ .

#### Chains II

- A denumerable increasing/ascending chain is a sequence  $\langle x_i, i \in \mathbb{N} \rangle$  such that  $x_0 \sqsubseteq x_1 \sqsubseteq \dots x_n \sqsubseteq x_{n+1} \dots i.e. \ \forall i < j \in \mathbb{N} \ . \ x_i \sqsubseteq x_j \ (\text{so } x \in \mathbb{N} \xrightarrow{\sim} \mathbb{P})$
- An increasing chain  $\langle x_i, i \in \mathbb{N} \rangle$  is *ultimately stationary* if and only if  $\exists \ell \in \mathbb{N} : \forall i \geq \ell : x_i = x_\ell$ .
- A poset  $\langle \mathbb{P}, \sqsubseteq \rangle$  is *noetherian* (or satisfies the *increasing chain condition* (also called ascending chain condition (ACC)<sup>1</sup>) if and only if any increasing chain is ultimately stationary (so that any strictly ascending chain is finite).
- The *descending chain condition* (*DCC*) is dual.

en.wikipedia.org/wiki/Ascending\_chain\_condition
en.wikipedia.org/wiki/Noetherian

<sup>&</sup>lt;sup>1</sup>(Voraussetzung des Teilerkettensatz) [Noether, 1921, Satz I], [Noether, 1927, Satz II]

CPO (Section **10.9**)

# Chain complete partial order (CPO)

- A complete partial order (CPO) or (countably chain-complete poset) is a poset  $\langle \mathbb{P}, \sqsubseteq, \bot, \sqcup \rangle$  with infimum  $\bot$  such that any denumerable ascending chain  $\langle x_i, i \in \mathbb{N} \rangle$  has a least upper bound  $\bigsqcup_{i \in \mathbb{N}} x_i \in \mathbb{P}$ .
- A dual-cpo is defined dually.

```
en.wikipedia.org/wiki/Complete_partial_order
en.wikipedia.org/wiki/Chain-complete_partial_order
```

This concludes our presentation of

- Pointwise extension
- Chains and CPOs

from Chapter 10 (Posets, lattices, and complete lattices)

#### Conclusion

- The poset representation ⟨P, ⊆⟩ of program properties P with an abstract implication ⊆ provides a unified theory of program properties and their abstraction
- Much more freedom and diversity is allowed in the choice of the possible encodings of abstract properties than with logic.
- [Aït-Kaci, Boyer, Lincoln, and Nasr, 1989] is an example of efficient implementation of finite lattices.
- In program verification and analysis, lattices need not be computer-representable, only their elements must be implemented.
- Posets, lattices, and complete lattices are used everywhere in abstract interpretation. It is essential to master these concepts!
